#### Internal, External, and Total Static Pressure Drop

Internal Static Pressure losses occur within mechanical equipment and are usually calculated by the manufacturer Examples include

- Dampers
- Filters
- Coils
- Heat exchangers
- Heat recovery devices (such as wheels, heat pipes)

External Static Pressure (ESP) losses occur within the system outside of the mechanical equipment and are usually calculated by the mechanical consultant. Examples include

Louvers

- Dampers (motorized, balancing, backdraft...)
- Duct fittings
- Duct transitions and elbows
- Air terminals
- Air valves and VAV boxes
- Filters

Total Static Pressure (TSP) loss is the sum of the internal and external losses in the system.

### **Steady Flow Equation**

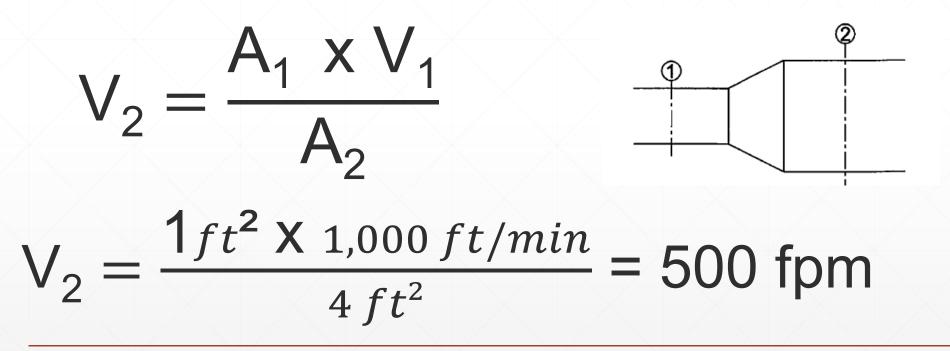

Volume flow rate = Area x air velocity

$$A_1 \times V_1 = A_2 \times V_2$$

Satwinder Singh / tagengineering.ca

#### **Example 1: Calculating Air Flow**

An airfow velocity through a duct with an area of 1ft<sup>2</sup> is 1,000 fpm. Determine the new airflow velocity when the area is increased to 4 ft<sup>2</sup>.

#### **Steady Flow Energy Equation**

$$P_{s1} + P_{V1} + P_{e1} + P_{p-}P_{f} = P_{s2} + P_{V2} + P_{e2}$$

 $P_{s1} + P_{V1} + P_{p-}P_{f} = P_{s2} + P_{V2} + P_{e2}$ 

# $P_{s1} + (V_1^2/2g) + P_{p-}P_f = P_{s2} + (V_2^2/2g)$

 $P_{s1}$  = Static Pressure of air at section 1 [ft]  $V_1^2$  = Velocity at section 1 [ft/sec]  $P_{e1}$  = Elevations at section 1 [ft]  $P_p$  = Pressure added by the fan [ft] G = gravitational constant [32.2 ft/sec<sup>2</sup>]

 $P_f$  = Pressure loss in duct by friction [ft]  $P_{s2}$  = Static Pressure of air at section 2 [ft]

Satwinder Singh / tagengineering.ca

#### **Example 2: Calculating Static Pressure Drop**

Given the Volume Flow Rate through a duct is 8,000 cfm, the friction loss from point 1 to point 2 is 0.5" WC. and the static pressure at point 1 is 2" WC.

 $P_{s1} + (V_1^2/2g) + P_{e1} + P_{p-}P_f = P_{s2} + (V_2^2/2g) + P_{e2}$ 

#### Velocity air pressure, P<sub>v</sub>

 $P_{\nu} = \rho \left( \frac{V^2}{1097} \right) = \left( \frac{V}{4005} \right)^2$ 

Pv in in water and V in ft/min

 $P_{\nu} = \rho \left( \frac{V^2}{1.414} \right) = \left( \frac{V}{1.29} \right)^2$ 

Pv in Pa and V in m/s

Mass Density ρ 62.4 lbm/ft3 and 999 kg/

Alternate units: Ft

$$P_{\text{Velocity}} = \frac{v^2}{2g}$$
 [ft], V = ft/sec

Pressure changes during flow in ducts.

# **TOTAL Pressure**

# $P_{Total} = P_{Velocity} + P_{Static}$

#### **Example 3: Calculate Pressure Loss**

Compute the lost pressure in a 6 in., 90-degree pleated elbow that has 150 cfm of air flowing through it. The ratio of turning radius to diameter is 1.5. Assume standard air.

Table 12-8: the loss coefficient: 0.43

$$\overline{V} = \frac{\dot{Q}}{A} = \frac{\dot{Q}}{(\pi/4)D^2} = \frac{(150)4(144)}{\pi(36)} = 764 \text{ ft/min}$$

$$\overline{V} = \frac{\dot{Q}}{A} = \frac{4.25}{(\pi/4)(0.1524)^2(60)} = 3.88 \text{ m/s}$$

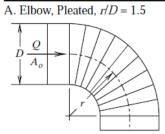

$$\Delta P_0 = C_0 \left(\frac{\overline{V}}{4005}\right)^2 = 0.43 \left(\frac{764}{4005}\right)^2 = 0.016 \text{ in. wg}$$

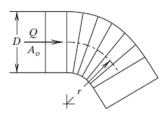

$$\Delta P_0 = C_0 \left(\frac{\overline{V}}{1.29}\right)^2 = 0.43 \left(\frac{3.88^2}{1.29}\right) = 3.89 \text{ Pa}$$

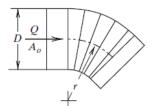

1" Water Guage = 248.84 Pa

Satwinder Singh / tagengineering.ca

### **Duct Accessories**

- 1. Turning vanes
  - Linear
  - Airfoil (More efficient)
- 2. Dampers
  - Parallel blades (open/close)
  - Opposed blades (modulate airflow)
  - Balancing
  - Motorized
  - Backdraft
- 3. Fire dampers
  - Type A (blades inside air stream)
  - Type B (blades outside air stream)
- 4. Electric duct heaters

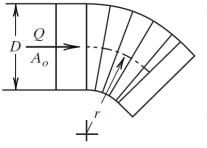

# **Turning Vanes**

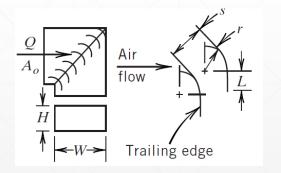

60 degree

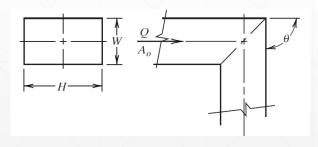

45 degree

B. Elbow, Mitered, with Single-Thickness Vanes, Rectangular

# Dampers

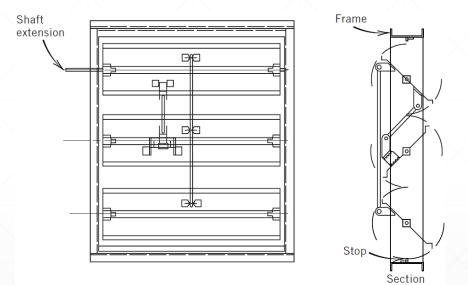

Figure 12-25 Typical opposed blade damper assembly.

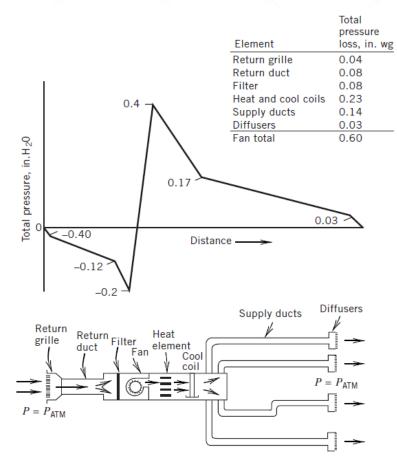

#### **Air Flow in Ducts**

Volume (Q) is a function of cross sectional

area (A) and velocity (V)

#### Q=AV

however, momentum, friction and turbulence must also be accounted for in the sizing method

#### **Static Pressure**

- Force required to overcome friction and loss of momentum due to turbulence
- As air encounters friction or turbulence, static pressure is reduced
- Fans add static pressure
- Static pressure is measured in Inches-water gauge
  - Positive pressure pushes air
  - Negative pressure draws air
- Straight ducts have a pressure loss of "w.g./100"

based on diameter and velocity

## **Equivalent Length**

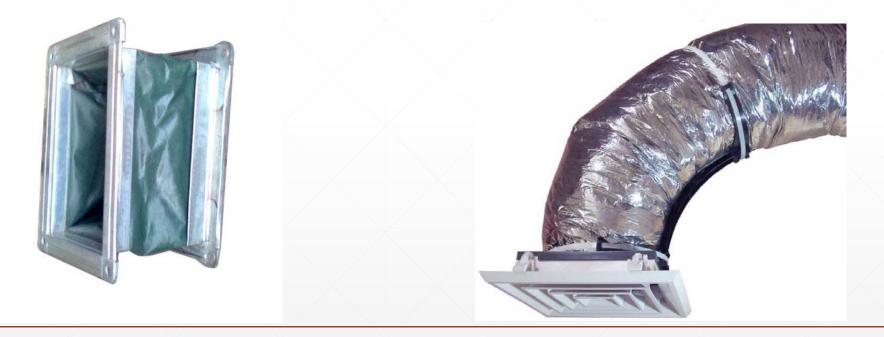

- Describes the amount of static pressure lost in a fitting that would be comparable to a length of straight duct

## **Duct Construction**

- Round ductwork is the most efficient but requires greater depth
- Rectangular ductwork is the least efficient but can be reduced in depth to accommodate smaller clearances
- Avoid aspect ratios greater than 5:1

# **Flex Ducts**

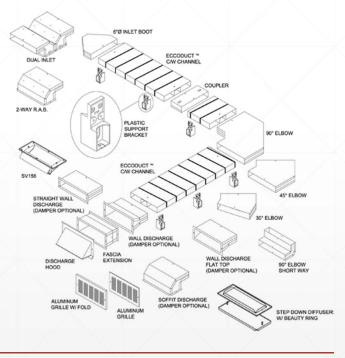

- Used to dampen noise when connecting to air terminals or mechanical equipment (i.e. bathroom fans)
- Typically only used for a max 5 foot length.
- Long runs of flex duct and elbows create large pressure drops in your system.

### **In-Slab Ducts**

- Typically seen in high rise buildings were no dropped ceilings are given near building exterior.
- Used to vent oven ranges, dryers, and sometimes bathroom fans.
- Can handle little airflow (approx. 50 CFM) due to size.
- Elbows always shown as two 45° joints to minimize pressure drop.
- Must be minimum of 2'-0" from structural bearing entities (columns, walls).

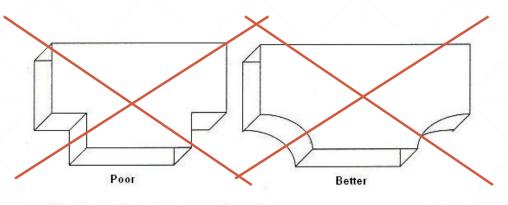

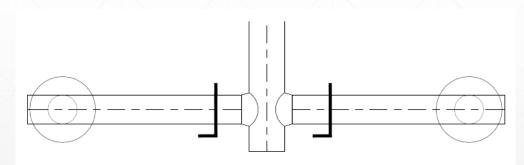

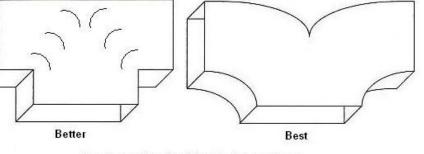

#### No "Bull Head" Tees

Airflow does not travel well when there is no clear path to follow. Instead

- show the duct continuing onward past the branch (as shown below),
- add turning vanes.
- use "pant leg" or wye type fitting (best option but most expensive)

Rectangular double 90 degree tees

Satwinder Singh / tagengineering.ca

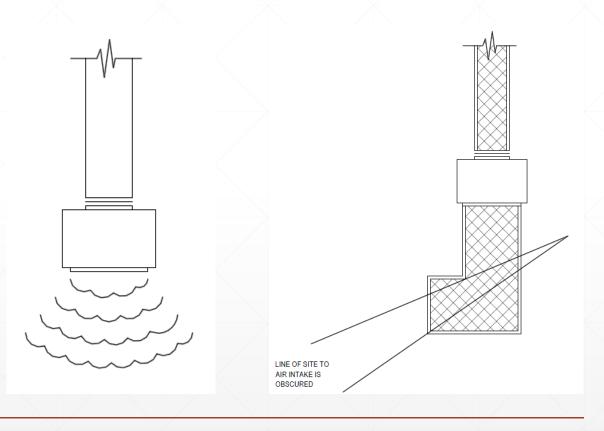

#### **Return Air Boot**

Used to reduce noise emanating from mechanical equipment in and adjacent to occupied spaces.

Should completely obscure line of sight to the air inlet. This forces the sound to bounce

Specified with 1" acoustic insulation.

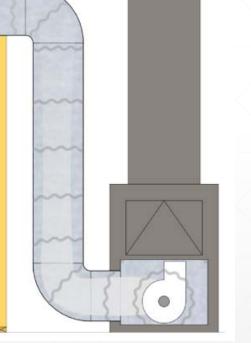

Typical "L" shaped boot is shown to the right.

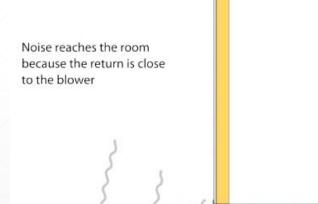

# **Z-Shape Return Air Boot**

#### Less common but more effective.

Satwinder Singh / tagengineering.ca

#### **Pressurized Plenum with Home Run Ducting**

Can be used where there are multiple duct diffusers with similar airflow requirements.

Each "home run" should be approximately the same length with the same pressure drop.

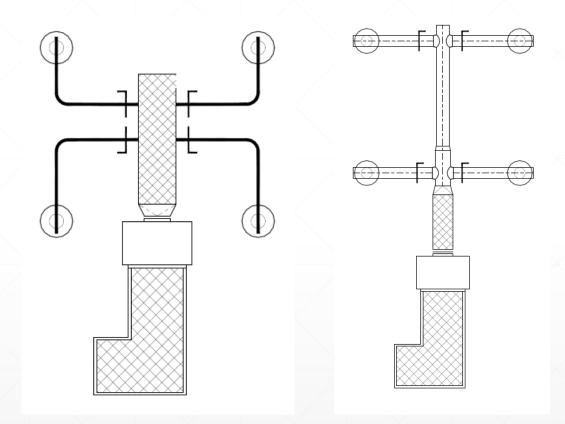

Do not take off ducts close to fan coil or at end of plenum.

Advantages:

- Can be used where there is very little ceiling height (i.e. running four 6"ø ducts as opposed to one 10"ø / 10"x8")
- Requires less overall space

Disadvantages

Cannot handle large pressure drops

# **Questions?**

Satwinder Singh / tagengineering.ca

24/01/2019

39

#### **Equal Friction Method**

- Presumes that friction in ductwork can be balanced to allow uniform friction loss through all branches
  - 1. Find effective length (EL) of longest run
  - 2. Establish allowed static pressure loss/100'

ΔP=100(SP)/E<sub>L</sub>

- 3. Size ducts
- 4. Repeat for each branch

Note: velocity must be higher in each upstream section

Satwinder Singh / tagengineering.ca

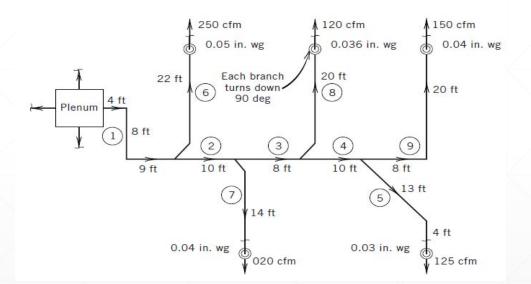

## **Assignment #2: Equal Friction Method**

Given:

- The system shown is supplied air by a rooftop unit that develops 0.25 in. wg total pressure external to the unit.
- The return air system requires 0.10 in. wg.
- The ducts are to be of round cross section, and the maximum velocity in the main run is 850 ft/min, whereas the branch velocities must not exceed 650 ft/min.

#### Size:

- The ducts using the equal-friction method.
- Show the location of any required dampers. Compute the total pressure loss for the system.

### **Equal Friction Method - Example**
